## **BACKGROUND OF THE INVENTION**

### **1. Related Applications**

This application is a continuation of U.S. Patent Application Serial No. 09/270,362, filed March 16, 1999, entitled, "Verification of Server Authorization to Provide Network Resources," now U.S. Patent No. 6,304,969, issued on October 16, 1999, which is hereby incorporated by reference.

### **2. The Field of the Invention**

The present invention relates to systems and methods for verifying the authorization of a server to provide network resources to a client. More specifically, the present invention relates to systems and methods whereby the client compares a random number encrypted in a message sent to the server with a random number encrypted in a message sent to the client from the server, wherein the client determines that the server is authorized if the random numbers are the same.

### **3. The Prior State of the Art**

During recent years, the use of computer networks to distribute information to users has increased dramatically. For example, the Internet is currently used for many purposes, including electronic commerce, delivery of news, entertainment, and education, to name just a few. Many Internet service providers ("ISPs") and content providers have found that accurate identification of users is necessary to support subscription services. When a client establishes communication with an ISP, the server at the ISP typically verifies that the client is recognized as one that has duly subscribed to the Internet service. Likewise, many World Wide Web ("Web") sites are available to users by subscription only. When a client attempts to access a subscription-based Web site, the client may be prompted to verify that it is authorized to receive content from the site.

1 Verification of the identity of clients has been accomplished in many ways. A  
2 simple example involves the client transmitting to the server a user name and a password  
3 that has been previously registered with the server. If the user name and password match a  
4 registered user name and password stored at the server, the client is allowed access to the  
5 network resources. More advanced security systems include, for example, transmitting a  
6 client machine identifier from the client to the server or other techniques whereby  
7 information associated with the client verifies the identity of the client.

8 Verifying the identity and authorization status of clients allows ISPs and content  
9 providers to collect subscription fees from users. Without a reliable system to verify  
10 authorization of clients, non-authorized users could access service, and legitimate users may  
11 have little incentive to pay for service.

12 There are some network configurations and business models that require security  
13 measures beyond the typical client-identification strategies described above. In some  
14 instances, it is desirable to identify the authorization of the server to provide network  
15 resources to the client. For a variety of reasons, suppliers or manufacturers of certain client  
16 systems may desire to allow only selected servers to provide network resources to their  
17 client systems. In one example, a provider of enhanced Internet, television, or other  
18 information or entertainment services may develop a client system specifically designed to  
19 receive its information or entertainment resources. In this example, the supplier of the client  
20 system can be seen primarily as the provider of the information or entertainment services,  
21 while the client system can be seen as a tool allowing users to gain access to the provider.

22 The traditional security strategy of providing user names, passwords, or other  
23 identifiers is inadequate when applied to the verification of authorization of a server to  
24 provide network resources. As can be easily understood, simple identifiers are not readily

1 applicable to configurations where a single or a small number of servers provide service to a  
2 large number of clients. In particular, if a server were to widely distribute an identifier to  
3 multiple clients, an imposter server could easily intercept the identifier and attempt to adopt  
4 the identity of the authorized server.

5 In addition, the entity that desires to control access by unauthorized servers is often  
6 not the client, but is instead the operator of the authorized server. When an unauthorized  
7 server attempts to gain access to client systems, the operator of the authorized server may  
8 not be aware of the attempt. Accordingly, if conventional security systems were the only  
9 available means of protection, the client system and the operator of the unauthorized server  
10 could collude to override the security system. As a result, any security system that is freely  
11 accessible by the operators of client systems or unauthorized servers could be breached  
12 relatively easily.

13 In view of the foregoing, what is needed is a system for verifying the identity or  
14 authorization of servers to provide network resources to client systems. It would be an  
15 advancement in the art to provide a system for verifying the authorization of servers that is  
16 not merely analogous to the conventional use of identifiers to verify the identity of clients.  
17 It would be particularly advantageous to verify the authorization of servers using a security  
18 system that cannot be readily accessed or overridden by an operator of the client system. It  
19 would also be desirable to combine such a system for verifying the authorization of servers  
20 with a system for verifying the identity of clients.  
21

## SUMMARY AND OBJECTS OF THE INVENTION

The present invention relates to systems and methods for verifying the authorization of a server to provide network resources to a client. The authorization process requires the server to decrypt a message generated by the client and to respond with an appropriate encrypted message. Authorized servers have the decryption key needed to decrypt the message, whereas unauthorized servers will be unable to decrypt the message or to return the appropriate encrypted message to the client. The system can be configured to prevent software operating on the client from enabling the functions of the client without proper server authorization or may otherwise override the security features. In addition, the process of verifying the authorization of the server can be combined with measures to verify the identity of the client.

According to one implementation of the invention, when a security counter, or timer, exceeds the value of an expiration count stored at the client or at other selected times, an authorization interrupt is generated. The other selected times for generating authorization interrupts may occur, for example, when the client is turned on or when software operating at the client generates a reauthorization signal. The authorization interrupt eventually disables some or all of the functions of the client unless the server is authorized within an allotted period of time. In response to the authorization interrupt, the client generates a client message that includes the value of the security counter, a client identifier, and a random number. The client message is encrypted using an encryption key and is transmitted to the server.

If the client message is received by an unauthorized server, the server is unable to decrypt the message and to access the encoded information included therein. When the client message is instead received by an authorized server, the server uses a decryption key

1 to decrypt the message. The server then decombines the value of the security counter, the  
2 client identifier, and the random number. Based on the value of the security counter, the  
3 server selects a new expiration count that will cause the client to again initiate the  
4 authorization process at a future time. The client identifier is compared against a client  
5 authorization database to determine the level of service that the client is authorized to  
6 receive. The level of service represents a level of functionality that the client is permitted to  
7 exhibit. The server generates an authorization code corresponding to the authorized level of  
8 service.

9 The server then creates a service message by combining the new expiration count,  
10 the authorization code, and the random number that was included in the client message. The  
11 server encrypts the service message and transmits it to the client. If the client message had  
12 been received by an unauthorized server, the message would have remained encrypted, such  
13 that the unauthorized server would not have gained access to the random number. Thus, any  
14 service message created by an unauthorized server will not include the original random  
15 number.

16 The client receives, decrypts, and decombines the service message. The random  
17 number included in the service message is compared with the random number included in  
18 the client message. If the random numbers are the same, the client assumes that the server is  
19 authorized to provide network resources. The new expiration count is written to an  
20 expiration count register and the new authorization code is written to an authorization  
21 register at the client. The client can then receive service from the server until the security  
22 count exceeds the new expiration count. If, however, the random numbers are not the same,  
23 the client assumes that the server is unauthorized, and the functions of the client are disabled  
24 according to the authorization interrupt after the allotted time has expired.

1 The client can include features that effectively prevent software executed on the  
2 client or the operator of the client from interfering with the server verification and  
3 authorization procedures of the invention. For example, the encryption key can be encoded  
4 on an integrated circuit at the client to prevent the key from becoming publicly known.  
5 Furthermore, the integrated circuit can have multiple encryption keys encoded thereon, with  
6 one of the keys being selected at random in each authorization procedure.

7 Certain registers at the client, such as those that specify the level of authorization of  
8 the client, can be controlled by the server without the intervention of software at the client.  
9 In particular, the server sends encrypted information to the client, where it can be decrypted  
10 by a decryption key encoded in an application-specific integrated circuit and then written to  
11 control registers. Thus, once the server verifies the identity of the client, the appropriate  
12 level of authorization can be maintained, even if the security of client software is breached.  
13 The authorized server, at its discretion, can also make any of a wide range of requests to the  
14 client to ensure that the client is authorized to receive network resources. For example, the  
15 client machine identifier can be independently verified by the server.

## **BRIEF DESCRIPTION OF THE DRAWINGS**

In order that the manner in which the above-recited and other advantages and objects of the invention are obtained, a more particular description of the invention briefly described above will be rendered by reference to specific embodiments thereof which are illustrated in the appended drawings. Understanding that these drawings depict only typical embodiments of the invention and are not therefore to be considered limiting of its scope, the invention will be described and explained with additional specificity and detail through the use of the accompanying drawings in which:

Figure 1 is a schematic diagram illustrating a network environment in which the invention may be implemented.

Figure 2 is a schematic diagram illustrating one embodiment of a client system for use with the invention.

Figure 3 is a schematic diagram depicting a client and a server interacting to verify the authorization of the server to provide network resources to the client.

Figure 4 is schematic diagram illustrating the client of Figure 3 in greater detail, including features for generating an encrypted client message and for comparing a random number contained in a service message with a random number contained in the client message.

Figure 5 is a schematic diagram illustrating the server of Figure 3 in greater detail, including features for decrypting the client message and generating an encrypted service message.

Figure 6 is a schematic diagram showing the manner in which an application-specific integrated circuit at the client can decrypt authorization information received from the server using an encoded decryption key according to one embodiment of the invention.

1 Figure 7 is a schematic diagram illustrating an alternative embodiment in which a  
2 smart card is used in conjunction with the client to verify that the server is authorized to  
3 provide network resources.

4 Figure 8 is a flow diagram depicting a method for generating an encrypted client  
5 message that includes a random number.

6 Figure 9 is a flow diagram illustrating a method for decrypting the client message at  
7 the authorized server and generating an encrypted service message that incorporates the  
8 random number.

9 Figure 10 is a flow diagram illustrating a method for decrypting the service message  
10 and comparing the random number included in the service message with the random number  
11 included in the client message.

**DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS**

The present invention relates to systems and methods for verifying the authorization of a server to provide network resources to a client. Repeatedly, and at specified times, the client initiates communication with the server and transmits a first encrypted message to the server. An authorized server has access to a decryption key that is used to decrypt the first encrypted message. If, however, the server is unauthorized, the message cannot be decrypted. When the first encrypted message has been successfully decrypted, the authorized server generates a second encrypted message and transmits it to the client. Based on the contents of the second encrypted message, the client can determine whether the server is authorized to provide the network resources.

The invention is described below by using diagrams to illustrate either the structure or processing of embodiments used to implement the system and method of the present invention. Using the diagrams in this manner to present the invention should not be construed as limiting of its scope. The embodiments of the present invention may comprise a special purpose or general purpose computer including various computer hardware, as discussed in greater detail below. The embodiments may further comprise multiple computers linked in a network environment.

Embodiments within the scope of the present invention include computer readable media having computer-executable instructions or data structures stored thereon. Such computer readable media can be any available media which can be accessed by a general purpose or special purpose computer. By way of example, and not limitation, such computer readable media can comprise RAM, ROM, EEPROM, CD-ROM or other optical disk storage, magnetic disk storage or other magnetic storage devices, or any other medium which can be used to store the desired computer-executable instructions or data structures

1 and which can accessed by a general purpose or special purpose computer. Combinations of  
2 the above should also be included within the scope of computer readable media. Computer-  
3 executable instructions comprise, for example, instructions and data which cause a general  
4 purpose computer, special purpose computer, or special purpose processing device to  
5 perform a certain function or group of functions. The computer-executable instructions and  
6 associated data structures represent an example of program code means for executing the  
7 steps of the invention disclosed herein.

8       Figures 1 and 2 and the following discussion are intended to provide a brief, general  
9 description of a suitable network and computing environment in which the invention may be  
10 implemented. Although not required, the invention will be described in the general context  
11 of computer-executable instructions, such as program modules, being executed by a personal  
12 computer. Generally, program modules include routines, programs, objects, components,  
13 data structures, etc. that perform particular tasks or implement particular abstract data types.

14       For illustration purposes, the invention is described herein in reference to the  
15 Internet, which represents one example of the network environments that are compatible  
16 with the invention. However, the principles disclosed herein are also applicable to  
17 substantially any other network environment in which a server provides network resources  
18 to a client. For example, a smart card or another PCMCIA device can be used as an  
19 intermediary device that communicates with the server and, in turn, with the client.

20       Figure 1 illustrates one embodiment of the architecture of an network environment in  
21 which the invention may be implemented. In this embodiment, multiple client systems 10  
22 communicate with a modem pool 12 by means of direct-dial, bi-directional data connections  
23 14, which may be conventional telephone lines, ISDN connections, connections supported  
24 by cable television providers, or any other suitable communications channel. Modem pool

12 may be any conventional modem pool, such as those that are currently used for providing access to the Internet and other wide area networks. For example, modem pool 14 may be provided by a local ISP. Thus, modem pool 14 may be coupled to a number of server computers, such as remote servers 16, via a conventional network infrastructure, which may be Internet infrastructure 18.

The systems and methods of verifying the authorization of a server can be practiced in network environments that combine information retrieval over the Internet with television viewing. As seen in Figure 1, at least some of client systems 10 can be associated with display devices 20 that serve a dual function. First, display devices 20 display graphical, computer-generated or computer-transmitted information provided by client systems 10. World Wide Web ("Web") pages retrieved from remote servers 16 represent one example of the graphical information that may be displayed on display devices 20. Second, television programming transmitted from television programming source 22 may also be displayed on display devices 20. Television programming source 22 may be any desired television broadcaster or delivery system. Accordingly, display device 20 may be a conventional television or may instead be a computer monitor adapted to display television programming. Indeed, the client system is optionally integrated in a television, or instead may be a self-contained unit. It is anticipated that, as high definition television ("HDTV") becomes common, embodiments of client terminal 26 will support HDTV. As used herein, "client terminal" 26 is defined to include a client system 10 and a display device 20.

Optionally, the system of Figure 1 can include a dedicated server 26 that is dedicated to providing Internet access to some or all of client systems 10. In this example, dedicated server 26 differs from modem pool 12 in that the dedicated server is specifically designed to service a particular type of client system 10 in contrast to serving any personal computer or

1 other computing device that can access the Internet. Furthermore, dedicated server 26  
2 optionally provides additional information services, such as television listings, enhanced  
3 television services, video and graphics delivery, etc.

4 Figure 2 depicts selected elements of one embodiment of a client system that may be  
5 used to implements portions of the invention. Client system 10 uses hardware and  
6 computer-executable instructions for providing the user with a graphical user interface, by  
7 which the user can access Internet resources, send and receive e-mail, and optionally receive  
8 other information services. Operation of client system 10 is controlled by a central  
9 processing unit (CPU) 28, which is coupled to an application-specific integrated circuit  
10 (ASIC) 30. CPU 28 executes computer-executable instructions designed to implement  
11 features of client system 10, including some of the steps of methods of the present invention.  
12 ASIC 30 contains circuitry which is used to implement certain functions of client system 10.  
13 For example, ASIC 30 may be coupled to an audio digital-to-analog converter 32 and to a  
14 video encoder 34, which provide audio and video output, respectively, to display device 20  
15 of Figure 1.

16 Client system 10 may further include an IR interface 36 for detecting infrared signals  
17 transmitted by a remote control input device, such as a hand-held device or a wireless  
18 keyboard. In response to the infrared signals, IR interface 36 provides corresponding  
19 electrical signals to ASIC 30. A standard telephone modem 38 and an ISDN modem 40 are  
20 coupled to ASIC 30 to provide connections to modem pool 12 and, via the Internet 18, to  
21 remote servers 16. While the client system illustrated in Figure 2 includes both a telephone  
22 modem and an ISDN modem, either one of these devices is sufficient to support the  
23 communications of the client system. Furthermore, in other embodiments, modems 38 and  
24 40 may be supplemented or replaced with cable modem 42 or another suitable

1 communications device. In other environments, communication may instead be established  
2 using a token ring or Ethernet connection.

3 Also coupled to ASIC 30 are a mask read-only memory (ROM) 44, a flash memory  
4 46, and a random access memory (RAM) 48. Mask ROM 44 is non-programmable and  
5 provides storage of computer-executable instructions and data structures. Flash memory 46  
6 may be a conventional flash memory device that can be programmed and erased  
7 electronically. Flash memory 46 may store Internet browser software as well as data  
8 structures. In one embodiment, a mass storage device 50 coupled to ASIC 30 is included in  
9 client system 10. Mass storage device 50 may be used to supply computer-executable  
10 instructions and data structures to other components of the client system or to receive data  
11 downloaded over the network. Mass storage device 50 may include any suitable medium for  
12 storing computer-executable instructions, such as magnetic disks, optical disks, and the like.

13 Application software and associated operating system software are stored in flash  
14 memory 46, or instead may be stored in any other suitable memory device, such as mask  
15 ROM 44 or mass storage device 50. The computer-executable instructions that, according to  
16 one embodiment of the invention, are used to monitor television viewing habits of a user and  
17 to construct a user profile that forms at least part of the basis for selecting advertisements are  
18 executed by CPU 28. In particular, CPU 28 executes sequences of instructions contained in  
19 one or more of mask ROM 44, flash memory 46, and RAM 48 to perform certain steps of  
20 the present invention that will be more specifically disclosed hereinafter.

21 In one embodiment of the invention, client system 10 is a WebTV set-top box  
22 manufactured by WebTV Networks, Inc. of Mountain View, California. In this case,  
23 dedicated server 26 of Figure 1 can be a WebTV server that provides Internet access and,

1 optionally, additional content and information. Alternatively, however, client system 10  
2 may be any of a variety of systems for receiving resources from a server.

3 Those skilled in the art will appreciate that the invention is not limited to the  
4 distributed computing environment and the client system illustrated in Figures 1 and 2. The  
5 invention may be practiced using other client system configurations, including personal  
6 computers, hand-held devices, multi-processor systems, microprocessor-based or  
7 programmable consumer electronics, network PCs, minicomputers, mainframe computers,  
8 and the like. In distributed computing environments, program modules may be located in  
9 both local and remote memory storage devices. Moreover, the authorization of servers to  
10 provide network resources can be verified in local area networks and wide area networks in  
11 addition to the network depicted in Figure 1. For example, a smart card, a PCMCIA device,  
12 or another intelligent peripheral can be used with the client to verify that the server is  
13 authorized to provide network resources according to an alternative embodiment.

14 Figure 3 illustrates selected functional features of one embodiment of a system that  
15 includes a client system and a server system. Client system 10 communicates with a  
16 network infrastructure 52 via a conventional network interface 54, which may be any of the  
17 modems or other communications devices described above in reference to Figure 2.  
18 Network infrastructure 52 may be the network architecture illustrated in Figure 1. Client  
19 system 10 includes a system enabler module 56 that controls the availability of some or all  
20 of the non-essential features of client system 10. "Non-essential features", as used herein,  
21 can include all of the features of client system 10 other than the basic functions that permit  
22 the client system to verify the identity of server 60. For example, when all of the non-  
23 essential features of client system 10 are disabled, the client system may still be capable of  
24 being turned on and accessing server 60 sufficiently to determine whether the server is

1 authorized to provide network resources, while being unable to retrieve and display  
2 information resources.

3 When client system 10 is periodically instructed to verify the authorization of server  
4 60, client message generation module 58 creates an encrypted client message that is sent to  
5 the server via network infrastructure 52. In one embodiment, the encrypted client message  
6 includes a random number selected by client system 10. A detailed description of the  
7 components of the client message and the methods for creating the client message and  
8 generating random numbers is provided below in reference to Figure 4.

9 Server system 60 of Figure 3 is authorized to provide network resources to client  
10 system 10. Thus, server system 60 is capable of decrypting the client message using client  
11 message decryption module 62. Based on the information included in the client message, a  
12 client authorization module 64 determines the level of functionality that client system 10 is  
13 authorized to exhibit and determines the next time that the client system is to repeat the  
14 authorization process. The random number encoded in the client message and information  
15 specifying the client's authorized level of functionality and the next time that the client is to  
16 initiate reauthorization process are included in an encrypted service message created by  
17 service message generation module 66. It is noted that had server system 60 been not  
18 authorized to provide network resources to client system 10, it would have been incapable of  
19 decrypting the client message. Any random number included in the client message would  
20 have remained inaccessible by the unauthorized client, and any service message could not  
21 have included the random number.

22 Client system 10 receives the encrypted service message and decrypts it using  
23 service message decryption module 68. A message comparator module 70 compares the  
24 contents of the service message with the contents of the client message. In particular, in

1 embodiments employing random numbers, message comparator module 70 determines  
2 whether the service message contains the same random number as the client message. If so,  
3 client system 10 assumes that server system 60 is authorized to provide network resources,  
4 and system enabler module 56 permits the authorized network resources to be received and  
5 displayed or otherwise communicated to a user of the client system. If, however, message  
6 comparator module 70 determines that the service message does not contain the same  
7 random number as the client message, client system 10 assumes that server system 60 is not  
8 authorized, and system enabler module 56 disables some or all of the non-essential functions  
9 of the client system.

10 Figures 4 and 5 illustrate in greater detail the elements and functions of the client  
11 systems and authorized server systems according to one embodiment of the invention.  
12 Figure 4 depicts client system 10, which is illustrated as having three functional subsystems:  
13 system enablement subsystem 72, client message generation subsystem 74, and message  
14 comparison subsystem 76. Likewise, Figure 5 depicts server system 60 as having three  
15 functional subsystems: client message decryption subsystem 78, client authorization  
16 subsystem 80, and service message generation subsystems 82. The foregoing subsystems  
17 are presented to conveniently describe the structure and functions of client system 10 and  
18 server system 60 in the following discussion. In particular, the subsystems of client system  
19 10 and server system 60 will be addressed below in the order that they are used in a typical  
20 process of verifying the authorization of the server system according to the invention.

21 Turning to Figure 4, client system 10 includes a security counter 84 and an  
22 expiration count 86 that together determine the moments at which the server verification  
23 procedures of the invention are initiated. Expiration count 86 has been set to specify when  
24 the server verification procedure is to begin. Security counter 84 is a timer or clock that

repeatedly increments the value of a security count until the security count reaches or exceeds the value of expiration count 86. Count comparator 88 monitors security counter 84 and, when the security count reaches or exceeds expiration count 86, the count comparator asserts an authorization interrupt. Security counter 84 and count comparator 88 constitute one example of a timing mechanism for specifying the times at which the client is to assert an authorization interrupt. In response to the authorization interrupt, a grace period timer 90 counts down an allotted grace period. If client system 10 fails to verify the authorization of server system 60 to provide network resources before the expiration of the allotted grace period, system enabler 91 will disable some or all of the non-essential functions of the client system.

The authorization interrupt asserted by count comparator 88 initiates activity in client message generation subsystem 74. In other circumstances, authorization interrupts can be created upon turning on client system 10 or at other times specified by software operating on the client system. To begin the process of verifying the authorization of server system 60, random number generator 92 generates a random number. In a preferred embodiment, random number generator 92 generates a unique signature based on asynchronous or external input conditions. For example, random number generator 92 can be a linear feedback shift register ("LFSR") seeded by asynchronous input according to techniques that will be understood by those skilled in the art. While numbers generated by an LFSR or by other conventional devices are technically pseudorandom, for purposes of this disclosure they will be designated as random. Random numbers generated by LFSRs or by other comparable systems provide the advantage of essentially eliminating the opportunity for other computers to generate random numbers in lockstep with client system 10.

1 Client system 10 further includes a client identifier 93, which can be a unique  
2 number associated with the client system. Client message generator 94 combines client  
3 identifier 93, the random number, and the current value of the security count, which  
4 indicates the current time. The value of the security count is a time identifier which permits  
5 the server system, as further described below, to specify the times at which the client system  
6 is to repeat the procedure for verifying the authorization of the server system. The value of  
7 the security count gives the server system a reliable understanding of the current time as  
8 measured by the client system.

9 The resulting client message is encrypted by client message encryptor 96 using an  
10 encryption key 98. In one embodiment, encryption key 98 is encoded in an integrated  
11 circuit, such as ASIC 30 of Figure 2. Encoding encryption key 98 in hardware as opposed to  
12 software greatly increases the difficulty of identifying the encryption key by those who  
13 might want to compromise the security of the system. In another embodiment, multiple  
14 encryption keys 98 can be encoded on the integrated circuit, further increasing the difficulty  
15 of learning the encryption key and determining which of the multiple keys is used in any  
16 specific instance. When multiple encryption keys are available, the particular key that is to  
17 be used can be selected in a random process. In addition, when there are multiple  
18 encryption keys 98, the encryption key that is used to encrypt a particular client message can  
19 be included in the client message for a purpose that is discussed below in reference to Figure  
20 5.

21 The encrypted client message is sent from client system 10 to server system 60 via  
22 network interface 54. Client message decryptor receives the client message through network  
23 interface 55 and decrypts it using the appropriate decryption key 102. When client system

1 10 includes only one encryption key 98, the selection of the decryption key 102 is relatively  
2 straightforward, since there will be only one decryption key.

3       However, when client system 10 includes multiple encryption keys 98, decryption  
4 may involve successively applying the corresponding decryption keys 102 to the client  
5 message in a trial and error process until one decryption key is found to successfully decrypt  
6 the message. Because the client message includes a random number, the security count, and  
7 the client identifier, a successful decryption can be determined when the decrypted client  
8 identifier matches one of the client identifiers registered at server system 60. It is noted that  
9 in some embodiments it may not be possible to reliably determine whether a message has  
10 been successfully decrypted by examining only the decrypted random number, and to a  
11 lesser degree, the security count, since the server system does not know what random  
12 number and security count to look for.

13       In some embodiments, there can be a very small risk that the client message  
14 decryptor 100 will apply one of the decryption keys 102 that does not correspond to the  
15 encryption key 98 used by client system 10, but will still determine that the decrypted client  
16 identifier matches one of the registered client identifiers. In other words, there can be a  
17 small possibility of a false positive decryption, in which the wrong decryption key will  
18 process the encrypted client identifier such that, by chance, it matches one of the registered  
19 client identifiers. If this were to occur, the random number would not be properly  
20 decrypted. Including the encryption key in the encrypted client message can eliminate this  
21 risk, however slight it might be. In particular, client message decryptor 100 can  
22 successively apply the multiple decryption keys 102 to the client message until the  
23 decrypted client message reveals an encryption key that corresponds to the decryption key  
24 just applied to the client message and a client identifier that matches a registered client

1 identifier. Nonetheless, for most purposes, the invention can be practiced with negligible  
2 risk of a false positive decryption result without including the encryption key in the client  
3 message. Indeed, in many cases, the efficiency losses incurred by increasing the size of the  
4 client message could outweigh any benefits that might be realized by eliminating the risk of  
5 a false positive decryption result.

6       Once the client message has been successfully decrypted, the message is  
7 decombined, or separated into its constituent parts, by client message decombiner 104 using  
8 the inverse mathematical operation that has been used to combine these values at client  
9 system 10. Client identifier 93, security count 106, and random number 108 are thereby  
10 extracted from the client message. In embodiments that establish the authorization level by  
11 which client system 10 is to receive service in addition to verifying the authorization of  
12 server system 60 to provide service, client identifier 93 is compared against client  
13 authorization database 110, which contains records of the authorization levels of the  
14 registered clients. The appropriate authorization code 112 for client system 10 is derived  
15 from client authorization database 110.

16       Server system 60 can perform any additional security checks to verify the identity of  
17 client system 10. For example, server system 60 can request that client system 10 securely  
18 transmit its client identifier 93 to compare it against the client identifier included in the  
19 client message. Those skilled in the art will recognize that other information can be  
20 transmitted from client system 10 to server system 60 in order to verify the validity of the  
21 client message.

22       Based on the value of security count 106, which specifies the time that the current  
23 authorization interrupt has been asserted, as measured by the client system, an expiration  
24 count selector 114 selects a new expiration count 116. New expiration count 116 can be

selected based on the particular user profile associated with client system 10 as defined in client authorization database 100, or can instead be selected to cause the reauthorization procedure to be repeated after a standard period of time.

A service message generator 118 then mathematically combines random number 108, authorization code 112, and new expiration count 116 to generate a service message. Since authorized server system 60 has successfully decrypted the client message, the service message generated thereby includes the same random number as the client message. The service message is encrypted by service message encryptor 120 using an encryption key 122. The resulting encrypted service message is transmitted to client system 10 via network interface 55.

Reference is now made to Figure 4, which illustrates elements of message comparison subsystem 76 according to this embodiment of the invention. The service message is received by a service message decryptor 124, which decrypts the message using a decryption key 126. A service message decombinder separates the service message into its constituent parts, which include the authorization code, the new expiration count, and the random number. The random number included in the service message is passed to random number comparator 130, where it compared with the random number included in the client message. If it is determined that the random numbers are the same, client system 10 assumes that server system 60 has decrypted the message and is therefore authorized to provide network resources to the client. If, however, client system 10 receives no service message or does not receive the original random number in the service message, the client system assumes that the server system is unauthorized.

If the server system is found to be authorized, client system enables or activates its functions based on the value of the authorization code. An appropriate authorization code

1 written to a control register in an application-specific integrated circuit, such as ASIC 30 of  
2 Fig. 2, permits the functions of the client system to operate. The authorization code can  
3 further indicate one of any number of levels of service or functionality. For example, when  
4 the invention is practiced in a WebTV set-top box or another client system that provides  
5 information and entertainment services to a user, the authorization code may activate the  
6 particular services that the user has subscribed to. Likewise, the new expiration count is  
7 written to a control register at the client system so as to again initiate the server verification  
8 procedure described herein when the security count exceeds the new expiration count.

9 If the server system has been determined to be unauthorized, grace period timer 90 of  
10 Figure 4 will eventually indicate that the allotted grace period has expired. At this point, the  
11 non-essential or any other set of functions of client system 10 are disabled until such time  
12 that an authorized server system is identified.

13 Figure 6 illustrates an embodiment of the invention wherein the authorization code  
14 and the new expiration count are written to control registers at an ASIC in a secure manner  
15 that essentially eliminates the opportunity of operators of the client system to override or  
16 otherwise tamper with the security features described herein. As has been described in  
17 reference to Figure 2, ASIC 30 is connected to a display device 20 and one or more memory  
18 devices 132. ASIC 30 can receive service messages and other information from the server  
19 system by means of network infrastructure 52 and network interface 54.

20 One of the functions of CPU 28 is writing control parameters to control registers 134  
21 of ASIC 30. Among the control parameters are the authorization code and the new  
22 expiration count. According to this embodiment, CPU 28 transmits the authorization code  
23 and the new expiration count to ASIC 30 in the encrypted form in which they were received  
24 from the server system. A private decryption key 126 is encoded on ASIC 30 and permits a

1 decryptor 124 encoded on ASIC to perform decryption of the authorization code and the  
2 new expiration count. It is noted that decryption key 126 and decryptor 124 of Figure 6 can  
3 be the same as the corresponding elements illustrated in Figure 5. Once the client system  
4 determines that the server system authorized, the new expiration count and the authorization  
5 code, having been decrypted, are written to secure registers 134b. In this manner,  
6 authorized server system 60 can securely write the new expiration count, the authorization  
7 code, and any other security parameters to secure control registers 134b without software  
8 operating on the client system having access to decryption key 126. Control parameters that  
9 do not pertain to the security features of the invention can be written to non-secure control  
10 registers 132a included in ASIC 30.

11 As illustrated in Figure 6, the security system of the invention can allow operating  
12 system software or other software operating on the client system to see only a limited  
13 amount of information. For example, as discussed herein, the authorization code and the  
14 expiration count can be written to secure control registers 134b. In addition, the  
15 authorization interrupt signal generated by count comparator 88 of Fig. 4 can be written to a  
16 control register 132 in one embodiment. Otherwise, the operation of the security system of  
17 this embodiment of the invention is not visible to the operating system, but is instead  
18 conducted by transmitting encrypted messages between the client system and the server  
19 system and decrypting the service message using a decryption key 126 encoded in hardware  
20 at the client system. Accordingly, rogue software or operators of the client system are  
21 unable to interfere with the operation of the security features of the invention.

22 Figure 7 illustrates an alternative embodiment, wherein the communication between  
23 the client and server is facilitated by an intelligent peripheral. As used herein, "intelligent  
24 peripheral" refers to any object or device associated with the client system, whether

1 embodied in hardware, software, or a combination of thereof, that is capable of verifying the  
2 authorization of a server to provide resources to the client. Examples of intelligent  
3 peripherals include smart cards or PCMCIA devices.

4 Intelligent peripheral 136 of Figure 7 communicates with server system 60 and  
5 verifies the authorization of the server system to provide network resources to client system  
6 10 in much the same way that the client system performed these functions in the  
7 embodiment disclosed above in reference to Figures 3-6. In effect, intelligent peripheral 136  
8 is an intermediary device that performs the function of verifying the authorization status of  
9 server system 60 on behalf of client system 10. Thus, intelligent peripheral 136 can include  
10 the functional components to perform the verification that are otherwise described herein as  
11 being included in client system 10.

12 After intelligent peripheral 136 determines that server system 60 is authorized (or not  
13 authorized) to provide resources to client system 10, the client system communicates with  
14 the intelligent peripheral. The communication between client system 10 and intelligent  
15 peripheral 136 informs the client system whether server system 60 is authorized, and further  
16 can include verification of the credentials of the intelligent peripheral, itself. Thus,  
17 intelligent peripheral 136 can have the functional components to communicate with client  
18 system 10, to verify its own authorization, and to verify the authorization of server system  
19 60 that are otherwise described herein as being included in the server system. System  
20 enabler module 56 responds to confirmation that server system 60 is authorized by enabling  
21 selected functions of client system 10 in a similar manner as described herein in reference to  
22 Figures 3-6.

23 The use of intelligent peripheral 136 can be useful when server system 60 is not  
24 immediately accessible, or when client system 10 and server system 60 are not

1 simultaneously available to communicate directly one with another. Intelligent peripheral  
2 136 can be constructed to prevent encryption keys or other sensitive information contained  
3 therein from being accessible to persons who might attempt to disassemble the intelligent  
4 peripheral and decode the sensitive information. Those skilled in the art, upon learning of  
5 the disclosure made herein, will understand how intelligent peripheral 136 can be  
6 constructed to prevent unauthorized access of information.

7 It is noted that intelligent peripheral 136 can be described as being a component of  
8 client system 10. Thus, unless otherwise indicated, any description or claim directed to a  
9 client system that verifies the authorization of a server system to provide resources  
10 encompasses the embodiment wherein an intelligent peripheral included in the client system  
11 performs some or all of the communication with the server system.

12 Figures 8-10 summarize the steps of one embodiment of the methods for verifying  
13 that a server system is authorized to provide network resources to a client system. Figure 8  
14 illustrates a method for composing a client message in response to an authorization interrupt.  
15 Figure 9 shows a method whereby an authorized server system receives the client message  
16 and composes a corresponding service message. Figure 10 illustrates a method for  
17 comparing the contents of the service message with the contents of the client message.

18 In step 140 of Figure 8, the security counter at the client system increments a  
19 security count until it reaches or exceeds the value of the expiration count. In step 142, the  
20 client system asserts an authorization interrupt, which will disable some or all non-essential  
21 functions of the client system after expiration of a grace period, unless the authorization of  
22 the server system is first verified. A random number is then generated in step 144 according  
23 to the techniques described herein. The client system combines the random number, the  
24 security count, and the client identifier to form a client message in step 146. In step 148, the

1 client message is encrypted as described herein. As shown at step 150, the encrypted  
2 message is then transmitted to the server system.

3 Referring to Figure 9, the server system receives the client message in step 152. The  
4 server system then decrypts the client message in step 154 and decombines the client  
5 message in step 156 as disclosed herein. Using the client identifier, the server system selects  
6 an authorization code to be associated with the client system as shown at step 158. The  
7 server system also selects a new expiration count in step 160, thereby indicating when the  
8 next reauthorization procedure should be initiated. In step 162, the server system combines  
9 the random number, the authorization code, and the new expiration count to form a service  
10 message. The service message is then encrypted in step 164 and transmitted to the client  
11 system in step 166.

12 As illustrated in Figure 10, the client system receives the service message according  
13 to step 168. The client system then decrypts the service message in step 170 and  
14 decombines the service message in step 172. As shown at step 174, the client system  
15 compares the random number contained in the service message with the original random  
16 number contained in the client message. According to decision block 176, if the random  
17 numbers are the same, the authorization of the server system to provide network resources to  
18 the client system has been verified, and the method advances to step 178, in which the  
19 authorization code causes selected functions of the client system to be enabled, whereby  
20 selected resources from the server can be received by the client. Next, in step 180, the new  
21 expiration count is set, and will cause the method of Figures 8-10 to repeat when the security  
22 count again exceeds the expiration count.

23 If the server system had been unauthorized, any service message generated thereby  
24 would not have included the random number. In this case, decision block 176 would be

1 answered in the negative, and the method would advance to step 182. In step 182, some or  
2 all of the non-essential functions of the client system would be disabled when the grace  
3 period expires without verification of the authorization of the server system, thereby  
4 preventing the client from receiving selected resources from the server.

5 The present invention may be embodied in other specific forms without departing  
6 from its spirit or other essential characteristics. The described embodiments are to be  
7 considered in all respects only as illustrative and not restrictive. The scope of the invention  
8 is, therefore, indicated by the appended claims rather than by the foregoing description. All  
9 changes which come within the range of equivalency of the claims are to be embraced  
10 within their scope.

11 What is claimed and desired to be secured by United States Letters Patent is:
